

cyber·feminist networks

Internet is a kind of ecosystem in which we store & access data (images, texts, emails...)

a server is a computer on which programs are "listening" if there are requests and answers them sending contents...

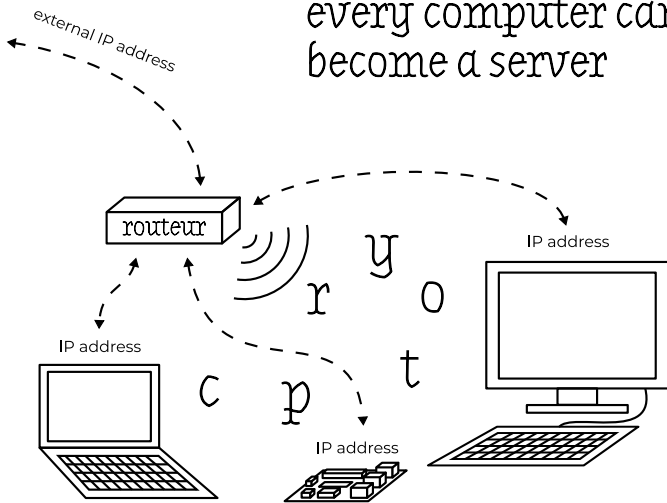

On Internet, companies (GAFAM) created privatised and centralised spaces, which business model is to sell our private data in exchange for free or even paying services. Internet isn't a safe space, but it can be safer.

create a safe·r ecosystem

renting a space on a server + renting a domain name
 -> allows to have one's own website but also emails and files
 There are also alternative and Free/Open Source services
 (see projects like De-google-ify Internet)

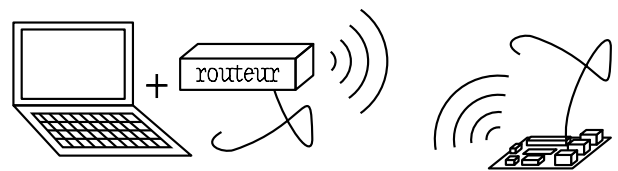

DIY server

every computer can become a server

situated networks

with a computer* we can create local networks to share files and documents in a delimited space & not on Internet.

*(or raspberry Pi, piratebox ... = mini-computers)

Local networks are the only ecosystems in which the infrastructure can be "self-controlled".
 A web server, even DIY always depends on other nodes in the network and of the largely provatised internet infrastructure.
